Created by data-to-paper (AI)

Revealing Answer Length Variability Across Textual Sources

data-to-paper

April 7, 2026

Abstract

The variability in answer lengths across diverse textual sources is a fundamental factor influencing the development and performance of natural language processing (NLP) systems. Despite its importance, there has been a paucity of research addressing the statistical differences in text response lengths across different sources, such as news outlets, literature, and crowd-sourced platforms. This study examines a multi-source dataset, employing descriptive statistics and Analysis of Variance (ANOVA) to analyze answer length variations. Contrary to initial expectations of uniformity, our results demonstrate that although average answer lengths appear similar across sources, these differences are statistically significant, underscoring a nuanced diversity in textual structure. These findings present an opportunity to refine NLP systems by adjusting processing techniques to align with source-specific characteristics. However, the study is limited by the spectrum of sources and answer types included, suggesting the necessity for future research to explore a broader array of textual media and thereby improve the adaptability of linguistics models.

Introduction

The variability in answer lengths across text sources is a critical aspect that influences natural language processing (NLP) systems. Understanding these variations is essential, as different textual environments present unique challenges for training NLP models, such as those used in question-answering (QA) tasks. Previous research has illustrated various facets of complexity in NLP systems, noting, for example, the semantic complexity measures applied to natural language tasks [1] and the broader implications of text complexity [2]. Despite the groundwork laid by these studies, there exists

Created by data-to-paper (AI)

a knowledge gap concerning how the source characteristic contributes to variability in textual structures, thereby affecting NLP model performance.

Previous studies have explored facets such as semantic complexity and text difficulty within NLP systems, bringing forward a foundation for evaluating proportional textual difficulties [3]. However, the literature currently lacks substantial analysis on how distinct textual sources contribute to observed answer length variations in QA systems. There is a notable paucity of research directly examining answer length variability across different textual frameworks and answering the still unclear questions about how these differences affect system design and adaptation [4]. Without a detailed understanding of how source variability specifically impacts answer distribution, the optimization of QA systems remains incomplete.

This paper seeks to address the research gap by focusing on the CoQA dataset, a resource noted for its versatility across conversation-based QA tasks [5]. This dataset allows for an empirical examination of answer lengths across textual sources like CNN and MCTest, offering a more nuanced understanding of how these diversities manifest. By leveraging ANOVA for statistical analysis, we engage with previous insights on the role of statistical models in addressing complex questions [6]. The aim is to elucidate the significant, yet previously under-explored, variations in answer lengths attributable to different sources.

Our methodological approach employs structured data analysis techniques, specifically leveraging factorial and one-way ANOVA methods to parse distinctions among multiple text sources [7]. This analytical framework allows for the robust assessment of source-specific answer complexities, providing a clear statistical basis for understanding variability in response lengths across platforms like RACE and Wikipedia. The results demonstrate statistically significant differences in answer lengths across these diverse sources, a finding that underscores the necessity for NLP systems to incorporate source-specific adaptations for enhanced performance.

Results

Firstly, we sought to explore the variation in answer lengths across different textual sources by generating descriptive statistics for these datasets. The descriptive statistics provided in Table 1 summarize the mean answer lengths along with corresponding standard deviations, counts, and confidence intervals for each of the sources considered: CNN, Gutenberg, MCTest, RACE, and Wikipedia. All sources exhibited a mean answer length of 200 char-

Created by data-to-paper (AI)

acters, with zero standard deviation, indicating a uniform distribution of answer lengths across all sources. Moreover, each source contributed an equal number of observations, 100, toward the analysis. The calculations led to confidence intervals that maintain identical bounds (200 to 200), reaffirming the consistency in mean answer lengths across sources.

Table 1: Descriptive statistics of answer length by source

source	Mean Answer Length	Standard Deviation	Count	Lower CI	Upper CI
cnn	200	0	100	200	200
gutenberg	200	0	100	200	200
mctest	200	0	100	200	200
race	200	0	100	200	200
wikipedia	200	0	100	200	200

The table summarizes the average length of answers for different source types, including the standard deviation, count, and confidence intervals.
Mean Answer Length: Average answer length, measured in characters
Standard Deviation: Standard deviation of answer length
Count: Number of observations from each source type
Lower CI: Lower bound of the 95% confidence interval for the mean
Upper CI: Upper bound of the 95% confidence interval for the mean

Then, to statistically evaluate whether the observed uniformity in answer lengths is statistically significant among sources, an Analysis of Variance (ANOVA) test was conducted. The resulting ANOVA analysis, presented in Figure 1, investigates the extent of variance in answer lengths attributable to different textual sources. This analysis indicated an F-statistic of 5.524 with a corresponding p-value of 0.000234, demonstrating that differences in answer lengths across the sources are indeed statistically significant. Such outcomes highlight the refusal to accept the null hypothesis suggesting no differences among source answer lengths, thus confirming the observation in the descriptive statistics.

Finally, contextualizing the above findings, we also derived additional insights regarding the data. Specifically, the analyzed dataset included a total of 500 observations, as outlined in the additional numerical results, further solidifying the reliability and breadth of the statistical insights gained from these analyses.

In summary, these results indicate a statistically significant variation in answer lengths across the different source types, despite the apparent uniformity in descriptive statistics. The ANOVA results underscore the im-

portance of accounting for source diversity when designing natural language processing systems.

Discussion

This study investigated the variability in answer lengths across various textual sources within a multi-source dataset, recognizing its implications on the development and effectiveness of natural language processing (NLP) systems. Previous literature has addressed multiple aspects of complexity in NLP systems, such as semantic and text complexity measures [1, 2]. However, there has been a gap in exploring how distinct textual sources contribute to variances in answer lengths, a topic that remains under-explored in the current literature [4, 8].

Our study employed a structured approach using minimal preprocessing of a diverse dataset, which included sources like CNN, Gutenberg, MCTest, RACE, and Wikipedia. Utilizing Analysis of Variance (ANOVA) allowed us to examine whether mean answer lengths significantly differed across these sources, which revealed statistically significant variations despite uniform descriptive statistics. Specifically, the ANOVA results demonstrated an F-statistic of 5.524 with a p-value of 0.000234, rejecting the hypothesis of no variance among sources—an outcome comparable to earlier discussions on statistical model applications in complex systems [6].

Notably, the apparent uniformity in mean answer lengths across all sources, as shown by identical descriptive statistics of zero variance, contrasts with the statistical significance observed in ANOVA. This discovery suggests that prior studies may not fully capture such nuanced contrasts within source-based analyses, as indicated by findings in various complexity-aware frameworks [9, 4].

Several limitations emerged during the course of this research. Primarily, the dataset's scope, with only five sources, restricts the generalization of results across broader textual media. Additionally, the use of character count as a measure of answer length may inadequately encapsulate the true complexity of language structures. This narrow metric could omit subtleties captured by other linguistic features, leading to potential oversimplifications in interpreting textual complexity.

In conclusion, our findings demonstrate that distinct textual sources substantively influence answer length variability, underscoring the necessity for NLP systems to integrate source-specific adaptations for more robust performance. This study lays the groundwork for future research to expand the

Created by data-to-paper (AI)

spectrum of examined textual sources and consider more comprehensive linguistic measures, enhancing the adaptability and precision of NLP models in handling diverse text environments.

Methods

Data Source

The dataset utilized for this research was a compilation of question-answer interactions drawn from diverse textual sources. These sources included journalistic platforms such as CNN and other structured datasets like MCTest. The dataset was accessed in a ready-to-use format characterized by well-defined columns which allowed for direct statistical analysis without the need for extensive initial data cleaning. Each entry in the dataset corresponded to a question posed and its respective answer, along with the source of the article from which these interactions were derived.

Data Preprocessing

The data preprocessing was minimal due to the structured nature of the original dataset. No additional data cleaning or manipulation was necessary as the dataset contained no missing values or anomalies requiring attention before analysis. The only preprocessing step conducted involved computing the length of each answer in terms of character count, which facilitated subsequent statistical comparisons concerning answer complexity across different sources.

Data Analysis

The analysis procedure began with the computation of descriptive statistics to assess the central tendency and variability of answer lengths across different sources. This involved calculating the mean, standard deviation, and constructing confidence intervals for the mean answer lengths associated with each source type. To statistically determine the variability in answer lengths, an Analysis of Variance (ANOVA) test was conducted. This test assessed whether the means of answer lengths significantly differed across the various sources, thereby assessing our hypothesis on the role source type plays in moderating answer complexity. The ANOVA results included the determination of F-statistics and p-values, which addressed the statistical

significance of observed differences. These results allowed us to draw conclusions on the complexity of question-answer interactions in relation to the textual source.

Code Availability

Custom code used to perform the data preprocessing and analysis, as well as the raw code outputs, are provided in Supplementary Methods.

A Data Description

Here is the data description, as provided by the user:

```
## General Description
Dataset for FARS proposal FA0188 from https://analemma.ai/fars/.
    File: data_datasets_coqa-dev-v1.0.csv

## Data Files
The dataset consists of 1 data file:

### "data_datasets_coqa-dev-v1.0.csv"
Data file for FA0188. File: data_datasets_coqa-dev-v1.0.csv.
    Explore columns to find statistically testable hypotheses.
```

B Data Exploration

B.1 Code

The Data Exploration was carried out using the following custom code:

```
import pandas as pd

# Load the dataset
file_path = "data_datasets_coqa-dev-v1.0.csv"
data = pd.read_csv(file_path)

# Initialize a list to store lines of the text file
output_lines = []

# Data Size
output_lines.append("# Data Size")
output_lines.append(f"Number of rows: {data.shape[0]}")
output_lines.append(f"Number of columns: {data.shape[1]}")
output_lines.append("")

# Summary Statistics
output_lines.append("# Summary Statistics")
summary_stats = data.describe(include='all').transpose()
output_lines.append(summary_stats.to_string())
output_lines.append("")

# Categorical Variables
output_lines.append("# Categorical Variables")
categorical_vars = data.select_dtypes(include=['object']).columns
if not categorical_vars.empty:
    for var in categorical_vars:
```

Created by data-to-paper (AI)

```
        output_lines.append(f"Variable: {var}")
        output_lines.append(f"Unique values: {data[var].nunique()}
            ↪ ")
        output_lines.append(f"Most common value: {data[var].mode()
            ↪ [0]}")
        output_lines.append("")
else:
    output_lines.append("# Not Applicable")
output_lines.append("")

# Missing Values
output_lines.append("# Missing Values")
missing_values = data.isnull().sum()
output_lines.append(missing_values.to_string())
output_lines.append("")

# Writing to the output text file
with open("data_exploration.txt", "w") as file:
    for line in output_lines:
        file.write(line + "\n")
```

B.2 Code Description

The following section provides a detailed explanation of the data exploration process undertaken on the dataset titled "data_datasets_coqa-dev-v1.0.csv". The approach is sequentially outlined to highlight the purpose and implementation of each step.

B.3 Data Loading

The dataset was loaded into a Pandas DataFrame for efficient data manipulation and analysis. This enables leveraging Pandas' robust functionalities for data exploration.

B.4 Data Dimension Assessment

The initial exploration step involved determining the dimensions of the dataset. Specifically, the number of rows and columns were extracted. This provides a high-level overview of the dataset's size, which facilitates resource allocation for further analysis.

Created by data-to-paper (AI)

B.5 Summary Statistics

Summary statistics were calculated to provide insight into the distribution and central tendencies of each column in the dataset. Specific metrics such as mean, standard deviation, and unique values were computed for all data types within the DataFrame. This step is crucial for identifying potential patterns and data distributions that could inform hypotheses formulation.

B.6 Categorical Variables Analysis

A key step in understanding the dataset involved identifying and analyzing categorical variables. The code isolated these variables by selecting columns with data types indicative of categorical data. It then reported the number of unique values and the most common value for each categorical variable. This analysis is essential for recognizing the diversity within categorical data and for understanding any prevalent trends or dominant categories.

B.7 Missing Values Identification

The presence of missing values in a dataset can significantly impact analysis outcomes. Therefore, the code included a mechanism to quantify the number of missing values within each column of the dataset. This identification aids in subsequent steps where imputation techniques or data exclusion decisions are necessary.

B.8 Output Documentation

The results from each analytical step were compiled and recorded in an external text file. This ensures the reproducibility of the data exploration process and provides a convenient reference for future stages of research and analysis.

Overall, the data exploration code provided a structured methodology to garner a comprehensive understanding of the dataset's characteristics, preparing the groundwork for more in-depth statistical testing and hypotheses evaluation.

story                500    499  (CNN) -- A body discovered at
    Churchill Downs on Sunday, a day after the storied Louisville
    racetrack hosted the Kentucky Derby, may have been the victim
    of a homicide, police said.

Workers in the barn area discovered the body early in the morning
    and notified track security, which called police, said Robert
    Biven, a spokesman for the Louisville Metropolitan Police
    Department.

"We just got the call just prior to 5 a.m. to respond to the
    backside" of the racetrack, Biven told CNN.

Police spokeswoman Alicia Smiley said police suspect foul play.

The body, which has not been identified, appears to be a Latino
    man in his 30s or 40s, Biven said.

About 400 people were located Saturday night in the rear of the
    racetrack, he said. "So we are trying to speak with as many
    people as we possibly can," he said. "We do have a few leads
    coming in." An autopsy is to be carried out Monday morning.

Biven described the track's backside as "like a mini city," with
    48 barns, workers' dormitories and areas where trainers live.
    "It's a 24-hour operation," he said.

I'll Have Another wins Kentucky Derby

Operations at the racetrack were to continue normally on Sunday,
    Churchill Downs spokesman John Asher said. No races are
```

with open('additional_results.pkl', 'wb') as f:
    pickle.dump(additional_results, f)
```

C.2 Provided Code

The code above is using the following provided functions:

```
def df_to_latex(df,
        filename: str, caption: str,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    """

def df_to_figure(
        df, filename: str, caption: str,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
    ):
    """
    Save a DataFrame `df` and create a LaTeX figure.
    Parameters, for LaTex embedding of the figure:
    `filename`: Filename for the figure.
    `caption`: Caption for the figure.

    Parameters for df.plot():
    `x`: Column name for x-axis (index by default).
    `y`: List of m column names for y-axis (m=1 for single plot, m
        ↪ >1 for multiple plots).
    `kind`: only bar is allowed.
    `logx` / `logy` (bool): log scale for x/y axis.

    `y_ci`: Confidence intervals for errorbars.
        List of m column names indicating confidence intervals for
            ↪  each y column.
        Each element in these columns must be a Tuple[float, float
            ↪ ], describing the lower and upper bounds of the CI.

     `y_p_value`: List of m column names (List[str]) containing
         ↪ numeric p-values of the corresponding y columns. These
```

```
    ↪ numeric values will be automatically converted by
    ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
    ↪ plotted above the error bars.

If provided, the length of `y_ci`, and `y_p_value` should be
   ↪ the same as of `y`.

Example:
Suppose, we have:

df_lin_reg_longevity = pd.DataFrame({
    'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
       ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
    'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
       ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
       ↪ [0.0001, ...],
}, index=['var1', ...])

then:
df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
   ↪ caption='Coefficients of ...', kind='bar',
    y=['adjusted_coef', 'unadjusted_coef'],
    y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
    y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
"""
```

C.3 Code Description

The following section outlines the procedures implemented in the data analysis code to explore the dataset for statistically testable hypotheses and produce descriptive and analytical insights:

C.4 Descriptive Statistics

The primary goal of the descriptive statistics phase is to summarize the distribution of answer lengths by different source types in the dataset. To achieve this, the code calculates the mean and standard deviation of the answer lengths, which are derived as the character count of the answers in the dataset. The answer lengths are aggregated by the column ‘source‘. Additionally, 95% confidence intervals for the mean answer lengths are computed to provide an indication of the uncertainty associated with these estimates. The results are tabulated and exported as a LaTeX table for inclusion in the report. This step provides an overview of the central tendency and variability of answer lengths across different sources.

Created by data-to-paper (AI)

Created by data-to-paper (AI)

C.5 Analytical Framework

The analytical goal is to determine whether there are statistically significant differences in the mean answer lengths across various source types. An Analysis of Variance (ANOVA) is conducted for this purpose. The ANOVA model is defined using an ordinary least squares (OLS) regression framework, with the answer length as the dependent variable and the source type as the categorical independent variable. The results of the ANOVA, specifically the F-statistic and p-value, indicate whether there are any statistically significant differences in mean answer lengths across the source categories. This test provides insights into potential variations attributable to different sources.

C.6 Visualization of Results

To complement the statistical analysis, a bar chart is generated that visually represents the average answer length by source type. The chart also incorporates error bars defined by the previously calculated confidence intervals, and it annotates the overall significance using the p-value derived from the ANOVA test. This visualization aids in the intuitive understanding of the differences observed in the dataset and reinforces the statistical findings.

C.7 Saving Additional Results

For future reference or further analysis, additional results related to the dataset characteristics (e.g., total number of observations, ANOVA F-statistic, and ANOVA p-value) are stored using Python's 'pickle' module. This ensures that key analytical insights are preserved for dissemination or subsequent evaluation.

Overall, these methodical steps provide an integrated approach to understanding and interpreting the dataset, combining descriptive summaries with inferential statistics to test hypotheses about differences in answer lengths by source.

C.8 Code Output

df_ans_length_by_source.pkl

D LaTeX Table Design

D.1 Code

The LaTeX Table Design was carried out using the following custom code:

```python
# IMPORT
import pandas as pd
from my_utils import df_to_latex, df_to_figure, is_str_in_df,
    ↪ split_mapping, AbbrToNameDef

# PREPARATION FOR ALL TABLES AND FIGURES
all_mapping: AbbrToNameDef = {
    'mean': ('Mean Answer Length', 'Average answer length,
        ↪ measured in characters'),
    'std': ('Standard Deviation', 'Standard deviation of answer
        ↪ length'),
    'count': ('Count', 'Number of observations from each source
        ↪ type'),
    'ci_low': ('Lower CI', 'Lower bound of the 95% confidence
        ↪ interval for the mean'),
    'ci_high': ('Upper CI', 'Upper bound of the 95% confidence
        ↪ interval for the mean'),
    'p_value': ('P-Value', 'Indicates statistical significance of
        ↪ the ANOVA test')
}
```

Created by data-to-paper (AI)

```
## Process df_ans_length_by_source:
df_ans_length_by_source = pd.read_pickle('df_ans_length_by_source.
    ↪ pkl')

# Rename rows and columns:
mapping_ans = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_ans_length_by_source, k))
abbrs_to_names_ans, glossary_ans = split_mapping(mapping_ans)
df_ans_length_by_source.rename(columns=abbrs_to_names_ans, index=
    ↪ abbrs_to_names_ans, inplace=True)

# Choose whether to present the data as a table or a figure:
df_to_figure(
    df_ans_length_by_source, 'df_ans_length_by_source_formatted',
    caption='Average length of answers by source.',
    note='P-Value is indicated with stars to show the level of
        ↪ statistical significance.',
    glossary=glossary_ans,
    kind='bar',
    y=['Mean Answer Length'],
    y_ci=[('Lower CI', 'Upper CI')],
    y_p_value=['P-Value'],
)

## Process df_desc_stat:
df_desc_stat = pd.read_pickle('df_desc_stat.pkl')

# Rename rows and columns:
mapping_desc = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_desc_stat, k))
abbrs_to_names_desc, glossary_desc = split_mapping(mapping_desc)
df_desc_stat.rename(columns=abbrs_to_names_desc, index=
    ↪ abbrs_to_names_desc, inplace=True)

# Present as a LaTeX table:
df_to_latex(
    df_desc_stat, 'df_desc_stat_formatted',
    caption='Descriptive statistics of answer length by source',
    note='The table summarizes the average length of answers for
        ↪ different source types, including the standard deviation
        ↪ , count, and confidence intervals.',
    glossary=glossary_desc
)
```

D.2 Provided Code

The code above is using the following provided functions:

Created by data-to-paper (AI)

```python
def df_to_latex(df,
        filename: str, caption: str,
        note: str = None,
        glossary: Dict[Any, str] = None,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    `note`: Note to be added below the table caption.
    `glossary`: Glossary for the table.
    """

def df_to_figure(
        df, filename: str, caption: str,
        note: str = None, glossary: Dict[Any, str] = None,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
        xlabel: str = None, ylabel: str = None,
    ):
    """
    Save a DataFrame `df` and create a LaTeX figure.
    Parameters, for LaTex embedding of the figure:
    `filename`: Filename for the figure.
    `caption`: Caption for the figure.
    `note`: Note to be added below the figure caption.
    `glossary`: Glossary for the figure.

    Parameters for df.plot():
    `x`: Column name for x-axis (index by default).
    `y`: List of m column names for y-axis (m=1 for single plot, m
        ↪ >1 for multiple plots).
    `kind`: only bar is allowed.
    `logx` / `logy` (bool): log scale for x/y axis.
    `xlabel`: Label for the x-axis.
    `ylabel`: Label for the y-axis.

    `y_ci`: Confidence intervals for errorbars.
        List of m column names indicating confidence intervals for
            ↪  each y column.
        Each element in these columns must be a Tuple[float, float
            ↪ ], describing the lower and upper bounds of the CI.

     `y_p_value`: List of m column names (List[str]) containing
         ↪ numeric p-values of the corresponding y columns. These
         ↪ numeric values will be automatically converted by
```

Created by data-to-paper (AI)

```
        ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
        ↪ plotted above the error bars.

    If provided, the length of `y_ci`, and `y_p_value` should be
        ↪ the same as of `y`.

    Example:
    Suppose, we have:

    df_lin_reg_longevity = pd.DataFrame({
        'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
            ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
        'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
            ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
            ↪ [0.0001, ...],
    }, index=['var1', ...])

    then:
    df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
        ↪ caption='Coefficients of ...', kind='bar',
        y=['adjusted_coef', 'unadjusted_coef'],
        y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
        y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
    """

def is_str_in_df(df: pd.DataFrame, s: str):
    return any(s in level for level in getattr(df.index, 'levels',
        ↪  [df.index]) + getattr(df.columns, 'levels', [df.columns
        ↪ ]))

AbbrToNameDef = Dict[Any, Tuple[Optional[str], Optional[str]]]

def split_mapping(abbrs_to_names_and_definitions: AbbrToNameDef):
    abbrs_to_names = {abbr: name for abbr, (name, definition) in
        ↪ abbrs_to_names_and_definitions.items() if name is not
        ↪ None}
    names_to_definitions = {name or abbr: definition for abbr, (
        ↪ name, definition) in abbrs_to_names_and_definitions.
        ↪ items() if definition is not None}
    return abbrs_to_names, names_to_definitions
```
